

Linear Modelling: Multiple Regression

14th of May 2021

R. Nicholls / D.-L. Couturier / M. Fernandes

Simple/single regression:
$$y = \alpha + \beta x + \varepsilon$$

Multiple regression:
$$\mathbf{y} = \beta_0 + \beta_1 \mathbf{x_1} + \beta_2 \mathbf{x_2} + \dots + \beta_n \mathbf{x_n} + \boldsymbol{\varepsilon}$$

$$y = X\beta + \varepsilon$$

Simple/single regression:
$$y = \alpha + \beta x + \varepsilon$$

Multiple regression:
$$\mathbf{y} = \beta_0 + \beta_1 \mathbf{x_1} + \beta_2 \mathbf{x_2} + \cdots + \beta_n \mathbf{x_n} + \boldsymbol{\varepsilon}$$

$$y = X\beta + \varepsilon$$

Parameter estimation:

Minimise sum of squares of residuals:

$$\sum_{i} \varepsilon_{i}^{2} \to \min$$

$$= \varepsilon^{T} \varepsilon = (\mathbf{v} - \mathbf{X} \mathbf{R})^{T} (\mathbf{v} - \mathbf{X} \mathbf{R}) \to \mathbf{m}$$

$$SS_{\text{error}} = \boldsymbol{\varepsilon}^{\mathrm{T}} \boldsymbol{\varepsilon} = (\boldsymbol{y} - \boldsymbol{X} \boldsymbol{\beta})^{\mathrm{T}} (\boldsymbol{y} - \boldsymbol{X} \boldsymbol{\beta}) \rightarrow \min$$

Solution:

$$\widehat{\boldsymbol{\beta}} = (\boldsymbol{X}^{\mathrm{T}}\boldsymbol{X})^{-1}\boldsymbol{X}^{\mathrm{T}}\boldsymbol{y}$$

Compare with the simple case:

$$\hat{\beta} = \frac{\sum_{i} (y_i - \bar{y})(x_i - \bar{x})}{\sum_{i} (x_i - \bar{x})^2} = \frac{\text{cov}(\boldsymbol{x}, \boldsymbol{y})}{\text{var}(\boldsymbol{x})}$$

Simple/single regression:
$$y = \alpha + \beta x + \varepsilon$$

Multiple regression:
$$\mathbf{y} = \beta_0 + \beta_1 \mathbf{x_1} + \beta_2 \mathbf{x_2} + \dots + \beta_n \mathbf{x_n} + \boldsymbol{\varepsilon}$$

$$y = X\beta + \varepsilon$$

Assumptions:

1. Model is linear in parameters.

2. Gaussian error model. $\varepsilon \sim N(\mathbf{0}, \sigma^2 \mathbf{I})$

3. Additive error model.

4. Independence of errors. $Cov(\varepsilon_i, \varepsilon_j) = 0$

5. Homoscedasticity. $Var(\boldsymbol{\varepsilon}|\boldsymbol{x}) = \sigma^2 \mathbf{I}$ and...

6. Lack of multicollinearity in the predictors (no highly correlated variables).

Simple/single regression:
$$\mathbf{y} = \alpha + \beta \mathbf{x} + \boldsymbol{\varepsilon}$$

Multiple regression:
$$\mathbf{y} = \beta_0 + \beta_1 \mathbf{x_1} + \beta_2 \mathbf{x_2} + \dots + \beta_n \mathbf{x_n} + \boldsymbol{\varepsilon}$$

$$y = X\beta + \varepsilon$$

Assumptions:

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \varepsilon$$

Simple/single regression:
$$\mathbf{y} = \alpha + \beta \mathbf{x} + \boldsymbol{\varepsilon}$$

Multiple regression:
$$\mathbf{y} = \beta_0 + \beta_1 \mathbf{x_1} + \beta_2 \mathbf{x_2} + \dots + \beta_n \mathbf{x_n} + \boldsymbol{\varepsilon}$$

$$y = X\beta + \varepsilon$$

Assumptions:

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \varepsilon$$

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_2^2 + \varepsilon$$

Simple/single regression:
$$\mathbf{y} = \alpha + \beta \mathbf{x} + \boldsymbol{\varepsilon}$$

Multiple regression:
$$\mathbf{y} = \beta_0 + \beta_1 \mathbf{x_1} + \beta_2 \mathbf{x_2} + \dots + \beta_n \mathbf{x_n} + \boldsymbol{\varepsilon}$$

$$y = X\beta + \varepsilon$$

Assumptions:

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \varepsilon$$
$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_2^2 + \varepsilon$$

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_1^2 + \varepsilon$$

Simple/single regression:
$$y = \alpha + \beta x + \varepsilon$$

Multiple regression:
$$\mathbf{y} = \beta_0 + \beta_1 \mathbf{x_1} + \beta_2 \mathbf{x_2} + \dots + \beta_n \mathbf{x_n} + \boldsymbol{\varepsilon}$$

$$y = X\beta + \varepsilon$$

Assumptions:

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \varepsilon$$

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_2^2 + \varepsilon$$

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_1^2 + \varepsilon$$

$$y = \beta_0 + \beta_1 x_1 + \beta_1^2 x_1^2 + \varepsilon$$

$$y = \beta_0 + \beta_1 x_1 + \beta_1^2 x_1^2 + \varepsilon$$

Multiple R-squared: 0.9353,

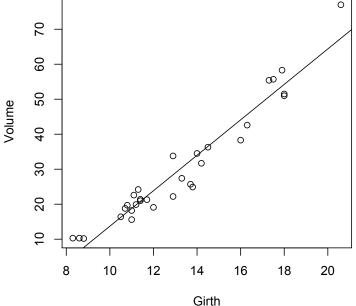

Example: *Predicting timber volume of cherry trees*

$$y = \alpha + \beta x + \varepsilon$$

```

Occam's Razor:

Among competing hypotheses, the one with the fewest assumptions should be selected

Parsimonious modelling:

Only choose a more complex model if the benefits are sufficiently substantial

We want:

- 1. The model that fits the data the best
- 2. Not to suffer from excessive overfitting

Objective solution: use information criteria

Akaike's Information Criterion:

$$AIC = 2k - 2\log(\hat{L})$$

k : number of parameters

 \hat{L} : maximum of the likelihood function.

The model with the smallest AIC is deemed the best.

Other information criteria exist.

Notably Bayesian Information Criterion (BIC), which more heavily penalises parameters. Careful with small sample sizes... corrections exist.

	R ²	AIC
$\mathbf{y} = \alpha + \beta \mathbf{x} + \boldsymbol{\varepsilon}$	0.9353	181.6
$\mathbf{y} = \beta_0 + \beta_1 \mathbf{x_1} + \beta_2 \mathbf{x_2} + \boldsymbol{\varepsilon}$	0.9480	176.9
$y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \beta_3 x_1 x_2 + \varepsilon$	0.9756	155.5
$\log(\mathbf{y}) = \beta_0 + \beta_1 \log(\mathbf{x_1}) + \beta_2 \log(\mathbf{x_2}) + \boldsymbol{\varepsilon}$	0.9777	-62.71
$\log(y) = \beta_0 + \beta_1 \log(x_1) + \beta_2 \log(x_2) + \beta_3 \log(x_1) \log(x_2) + \varepsilon$	0.9778	-60.88
$\log\left(\frac{y}{x_1^2 x_2}\right) = \beta_0 + \varepsilon$	NA	-66.34
$y = \beta_1 x_1^2 x_2 + \varepsilon$	0.9950	146.6
Response: y = Volume		

Predictor: $x_1 = Girth$

Predictor: $x_2 = Height$

31

Sometimes selecting the best model can be difficult (time consuming & subjective)

Especially when there are a huge number of independent variables

Stepwise Regression – automatically selects "the best" model:

- Start from a given model
- Add or remove terms one at a time
- Score model (AIC)
- Repeat until optimal solution is found

Two options:

- Forward selection start from simple model and add terms one at a time
- Backward elimination start from a complex model and remove terms one at a time

Warning:

These strategies can lead to different models being selected Neither strategy guarantees the optimal solution, but they are quick

Stepwise Regression:

Example: Swiss fertility and socioeconomic indicators

Regress Fertility against all available indicators:

```
Estimate Std. Error t value Pr(>|t|)
            66.91518
                    10.70604 6.250 1.91e-07 ***

F-statistic: 24.42 on 4 and 42 DF, p-value: 1.717e-10
```

- Compared to before stepwise regression, R² is lower, and RSE is higher
- AIC favoured the model with fewer parameters.

Non-linear models:

Motivating example: *Predicting timber volume of cherry trees*

$$y = \beta_0 x_1^{\beta_1} x_2^{\beta_2} + \varepsilon$$

Response: y = Volume

Predictor: $x_1 = Girth$

Predictor: x_2 = Height

Can't solve using standard regression approaches.

Instead, use a library that can estimate parameters for non-linear models, e.g. "nls" in R.

Con's:

- May require initial parameter estimates
- May not find globally optimal solution depends on initial parameter estimates
- May not converge at all
- Slower iterative approach
- Becomes slower and less reliable as the function becomes more complex

Pro's:

Allows dealing with a wider class of model functional forms

Non-linear models:

Motivating example: *Predicting timber volume of cherry trees*

$$y = \beta_0 x_1^{\beta_1} x_2^{\beta_2} + \varepsilon$$

Response: y = Volume

Predictor: $x_1 = Girth$ Predictor: $x_2 = Height$

Can't solve using standard regression approaches.

Instead, use a library that can estimate parameters for non-linear models, e.g. "nls" in R.

Parameters:

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 '' 1

Residual standard error: 2.533 on 28 degrees of freedom

Number of iterations to convergence: 5 Achieved convergence tolerance: 8.255e-07

AIC = 150.4

Parameters:

Estimate Std. Error t value Pr(>|t|)

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

Residual standard error: 4.216 on 29 degrees of freedom

Number of iterations to convergence: 10 Achieved convergence tolerance: 8.673e-06

AIC = 181.1

Note: poor parameter interpretation

Final Message:

Linear regression is well-suited to dealing with continuous data...

However it is also suited to:

- Discrete data (e.g. Poisson, Binomial)
- Categorical data (indicator variables, factors)
- Binary data (e.g. Bernoulli)

We have already seen a linear model be used to estimate the mean...

Consider similarities to other techniques:

One-sample Student's t-test:
$$Y_i = \mu + \varepsilon_i$$

Two independent sample t-test:
$$Y_{i(g)} = \mu + \delta_g + \varepsilon_{i(g)}$$
 One-way ANOVA:

Two-way ANOVA:
$$Y_{i(gk)} = \mu + \delta_g + \delta_k + \delta_{gk} + \varepsilon_{i(gk)}$$

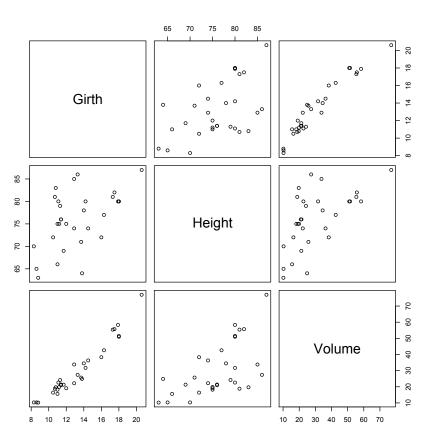

These are all linear models! The only difference is in the questions we ask... Linear modelling is extremely flexible.

What to use and when:

	Multiple regressors	Non-Gaussian error model	Non-linear data	Autocorrellated data
Simple regression				
Multiple regression	✓			
Generalised linear model	•	V		
Non-linear model	✓	V	V	
Time series analysis				V
